# INTRODUCTION TO PARALLEL COMPUTING

Dr. Lavika Goel

#### The Data Communication Argument

- As the network evolves, the vision of the Internet as one large computing platform has emerged.
- In many other applications (typically databases and data mining) the volume of data is such that they cannot be moved.
- Any analyses on this data must be performed over the network using parallel techniques.

# Scope of Parallel Computing Applications

- Parallelism finds applications in very diverse application domains for different motivating reasons.
- These range from improved application performance to cost considerations.

## **Commercial Applications**

- Data mining and analysis for optimizing business and marketing decisions.
- Large scale servers (mail and web servers) are often implemented using parallel platforms.
- Applications such as information retrieval and search are typically powered by large clusters.

## **Applications in Computer Systems**

- Network intrusion detection, cryptography, multiparty computations are some of the core uses of parallel computing techniques.
- Embedded systems increasingly rely on distributed control algorithms.
- A modern automobile consists of tens of processors communicating to perform complex tasks for optimizing handling and performance.

# PARALLEL PROGRAMMING PARADIGMS

## Why Parallelism

- Faster, of course
  - Finish the work earlier
    - Same work in less time
  - Do more work
    - More work in the same time

## How to parallelize

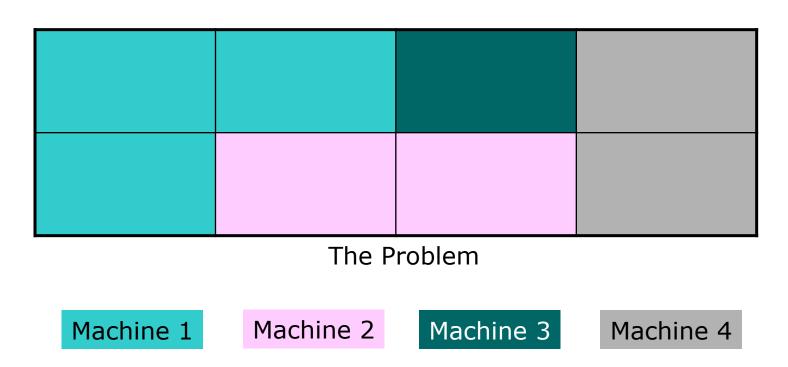

- Break down the computational part into small pieces
- Assign the small jobs to the parallel running processes
- May become complicated when the small piece of jobs depend upon others

## Writing a Parallel Program

- If you are starting with an existing serial program, debug the serial code completely
- Identify which parts of the program can be executed concurrently:
  - Requires a thorough understanding of the algorithm
  - Exploit any parallelism which may exist
- Decompose the program:
  - Task Parallelism
  - Data Parallelism
  - Combination of both

## Task (Functional) Parallelism

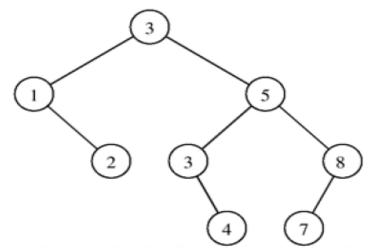

Decomposing the problem into different processes which can be distributed to multiple processors for simultaneous execution

Good to use when there is not static structure or fixed determination of number of calculations to be performed

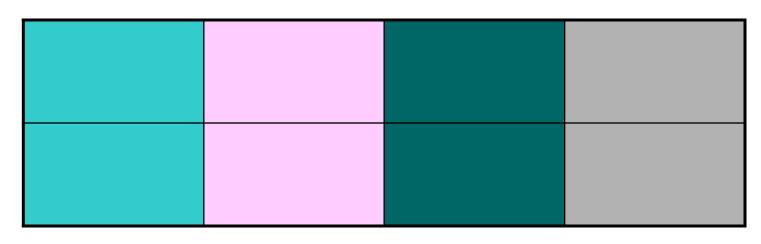

#### **Task Parallelism**

- The computations in any parallel algorithm can be viewed as a task dependency graph
- Tasks are mapped statically to help optimize the cost of data movement among tasks
- This type of parallelism that is naturally expressed by independent tasks in a task-dependency graph is called task parallelism.

## Data (Domain) Parallelism

- Partitioning the problem's data domain and distributing portions to multiple processors for simultaneous execution
- Good to use for problems where:
  - Code is static
  - Data domain is fixed but computation within various regions of the domain is dynamic

The Problem

Machine 1

Machine 2

Machine 3

Machine 4

- In the data-parallel model, the tasks are statically or semi-statically mapped onto processes and each task performs similar operations on different data.
- This type of parallelism that is a result of identical operations being applied concurrently on different data items is called *data* parallelism.
- The work may be done in phases and the data operated upon in different phases may be different.

- Data-parallel computation phases are interspersed with interactions to synchronize the tasks or to get fresh data to the tasks.
- The decomposition of the problem into tasks is usually based on data partitioning because a uniform partitioning of data followed by a static mapping is sufficient to guarantee load balance.

$$\begin{pmatrix} A_{1,1} & A_{1,2} \\ A_{2,1} & A_{2,2} \end{pmatrix} \cdot \begin{pmatrix} B_{1,1} & B_{1,2} \\ B_{2,1} & B_{2,2} \end{pmatrix} \rightarrow \begin{pmatrix} C_{1,1} & C_{1,2} \\ C_{2,1} & C_{2,2} \end{pmatrix}$$

$$(a)$$

$$\text{Task 1: } C_{1,1} = A_{1,1}B_{1,1} + A_{1,2}B_{2,1}$$

$$\text{Task 2: } C_{1,2} = A_{1,1}B_{1,2} + A_{1,2}B_{2,2}$$

$$\text{Task 3: } C_{2,1} = A_{2,1}B_{1,1} + A_{2,2}B_{2,1}$$

$$\text{Task 4: } C_{2,2} = A_{2,1}B_{1,2} + A_{2,2}B_{2,2}$$

$$(b)$$

- Data parallel computation:
  - Perform the same operation on different items of data at the same time; the parallelism grows with the size of the data.

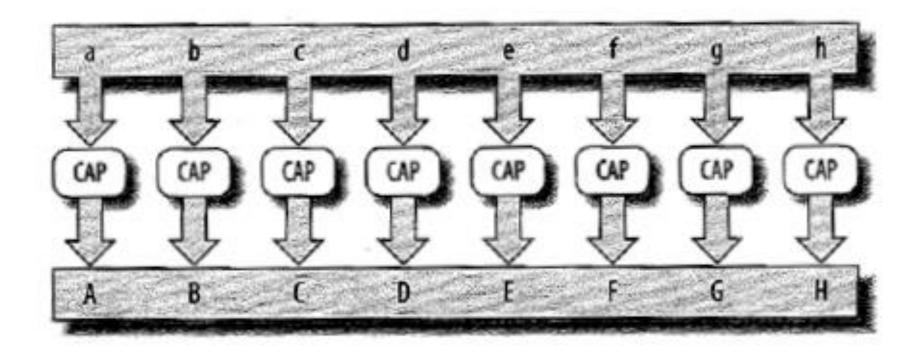

- Task parallel computation:
  - Perform distinct computations -- or tasks -- at the same time. If the number of tasks is fixed, the parallelism is not scalable.

- FOR each CPU in parallel computing environment
  - Retrieve next task from task queue
  - Create a thread and provide it with the retrieved task
  - Start the created thread
- END FOR

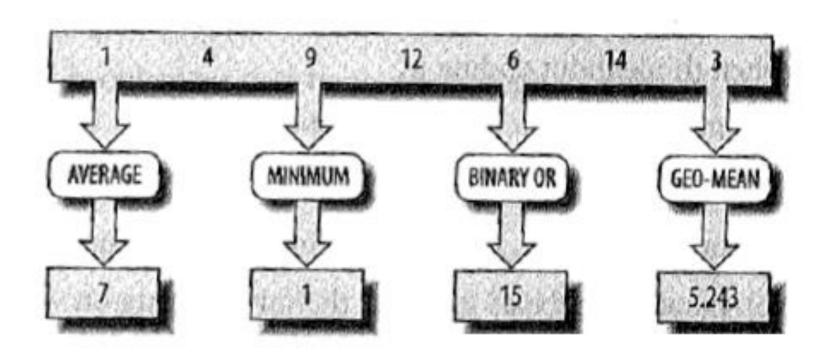

- lower\_limit = 0
- upper\_limit = 0
- FOR each CPU in parallel computing environment
  - lower\_limit = upper\_limit + 1
  - upper\_limit = upper\_limit + round(d.length/ no\_of\_cpus)
  - Create a thread and provide it with lower\_limit and upper\_limit data array indexes
  - Start the created thread
- END FOR

- Data parallelism:
  - The same task run on different data in parallel
- Task parallelism:
  - Different tasks running on the same data
- Hybrid data/task parallelism:
  - A parallel pipeline of tasks, each of which might be data parallel

#### **Data or Task Parallel ??**

#### **Data or Task Parallel ??**

Data Parallelism	Task Parallelism
Same operations are performed on different subsets of same data structure.	Different operations are performed on the same or different data in parallel to fully utilize the resources.
Synchronous computation	Asynchronous computation
Speed up is more as there is only one execution thread operating on all sets of data.	Speed up is less as each processor will execute a different thread or process on the same or different set of data.

#### When Data / Task Parallelism

- Choose the data-parallel threading model for compute-intensive loops, that is, where the same, independent operation is performed repeatedly.
  - Data parallelism implies that the same independent operation is applied repeatedly to different data.
- Choose the task-parallel model when independent threads can readily service separate functions.
  - Task-level concurrency calls for independent work encapsulated in functions to be mapped to individual threads, which execute asynchronously.

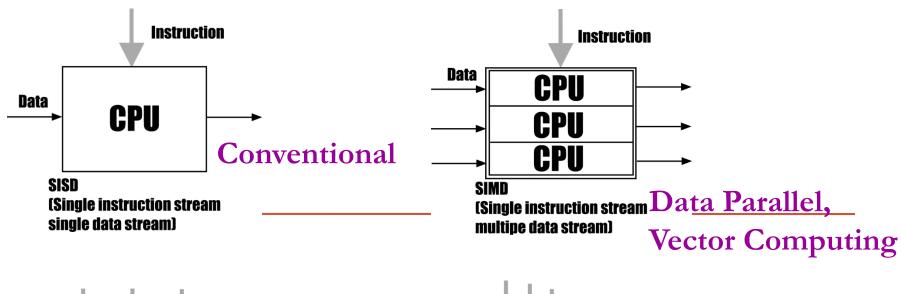

## **Elements of a Parallel Computer**

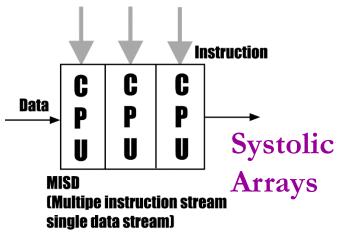

- Hardware
  - Multiple Processors
  - Multiple Memories
  - Interconnection Network
- System Software
  - Parallel Operating System
  - Programming Constructs to Express/Orchestrate Concurrency
- Application Software
  - Parallel Algorithms

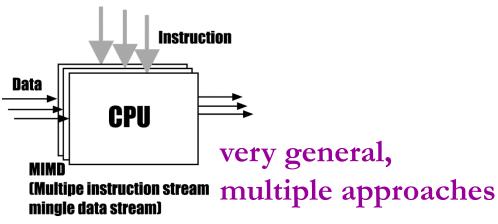

## **Parallel Computing Platform**

- Logical Organization
  - The user's view of the machine as it is being presented via its system software
- Physical Organization
  - The actual hardware architecture
- Physical Architecture is to a large extent independent of the Logical Architecture

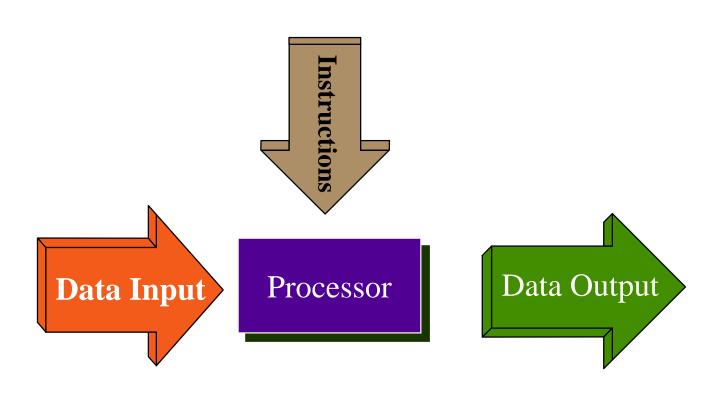

## Flynn's Classification

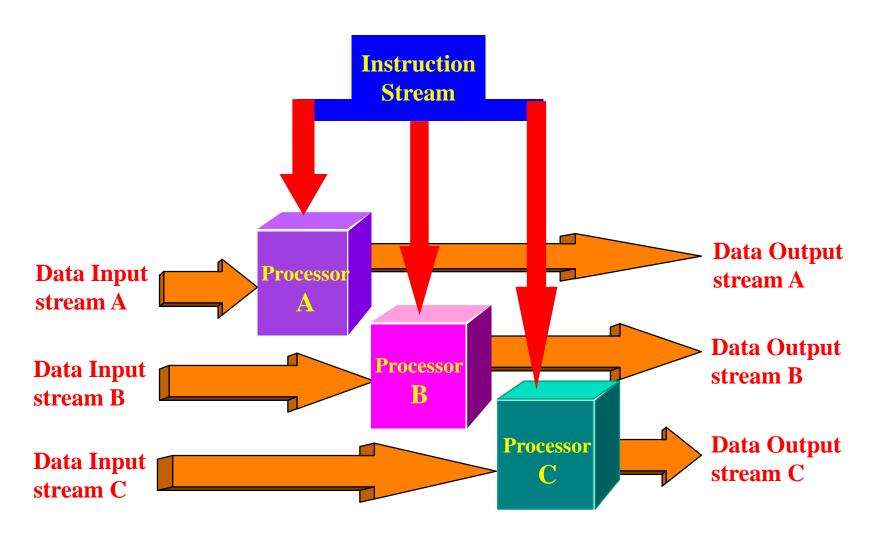

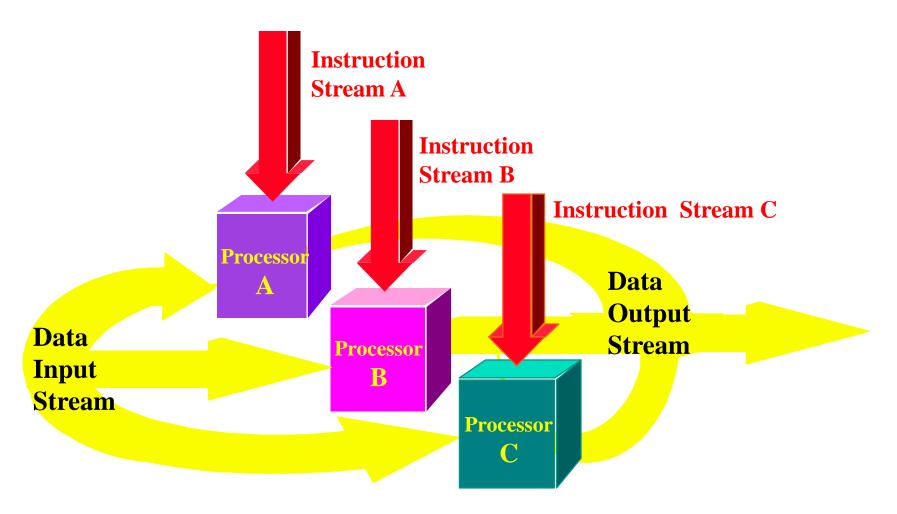

#### Single Instruction, Single Data (SISD)

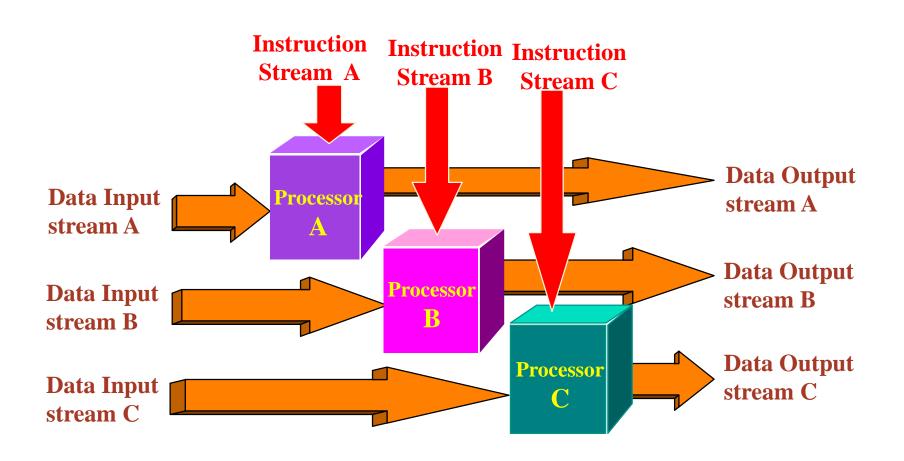

#### Single Instruction, Multiple Data (SIMD)

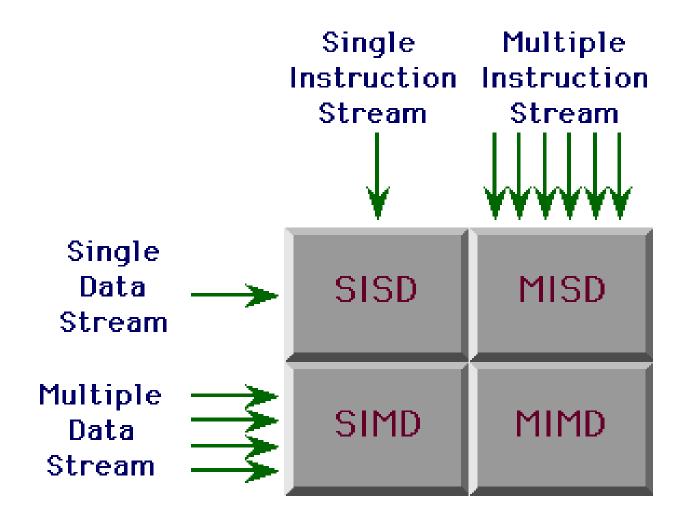

#### Multiple Instruction, Single Data (MISD)

#### Multiple Instruction, Multiple Data (MIMD)

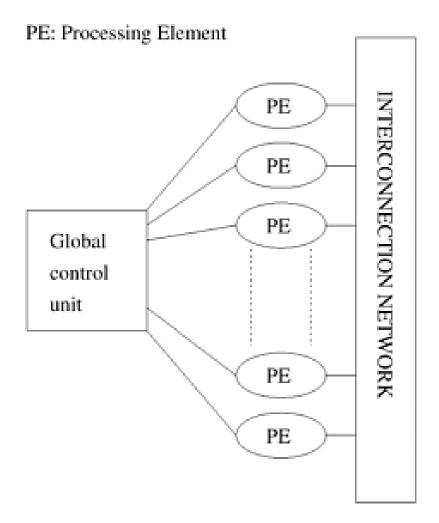

## Flynn's Classification

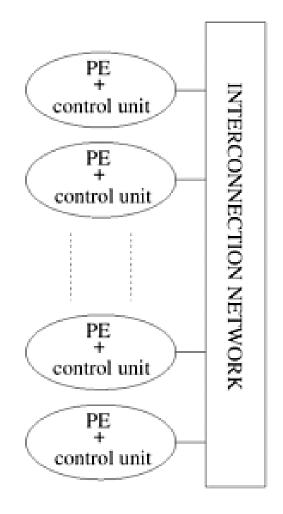

#### **Control Structure of Parallel Programs**

- If there is a single control unit that dispatches the same instruction to various processors (that work on different data), the model is referred to as single instruction stream, multiple data stream (SIMD).
- If each processor has its own control unit, each processor can execute different instructions on different data items. This model is called multiple instruction stream, multiple data stream (MIMD).

#### SIMD and MIMD Processors

(a) (b)

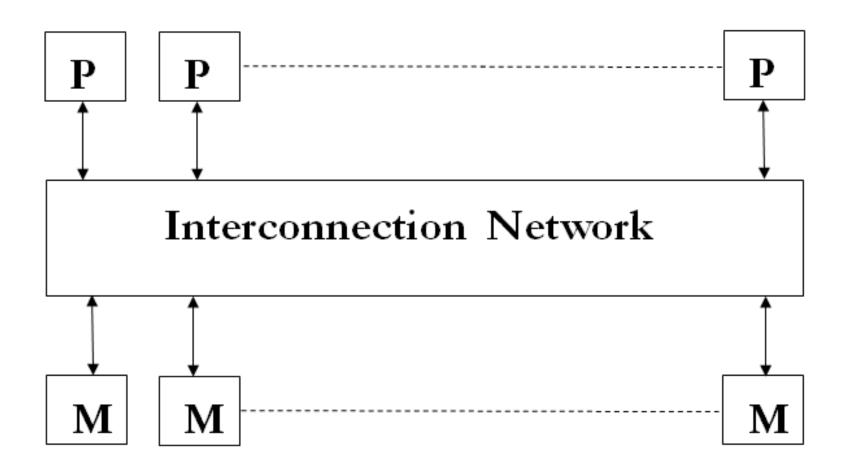

#### **Communication Model of Parallel Platforms**

- There are two primary forms of data exchange between parallel tasks - accessing a shared data space and exchanging messages.
- Platforms that provide a shared data space are called shared-address-space machines or multiprocessors.
- Platforms that support messaging are also called message passing platforms or multicomputers.

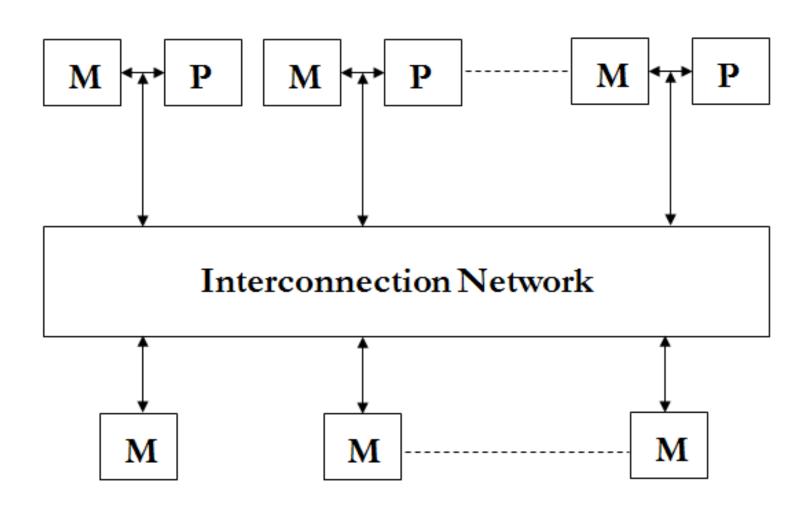

## **Shared-Address-Space Platforms**

- Part (or all) of the memory is accessible to all processors.
- Processors interact by modifying data objects stored in this shared-address-space.
- If the time taken by a processor to access any memory word in the system (global or local) is
  - identical, then the platform is classified as a uniform memory access (UMA),
  - not identical, then its classified as non-uniform memory access (NUMA) machine.

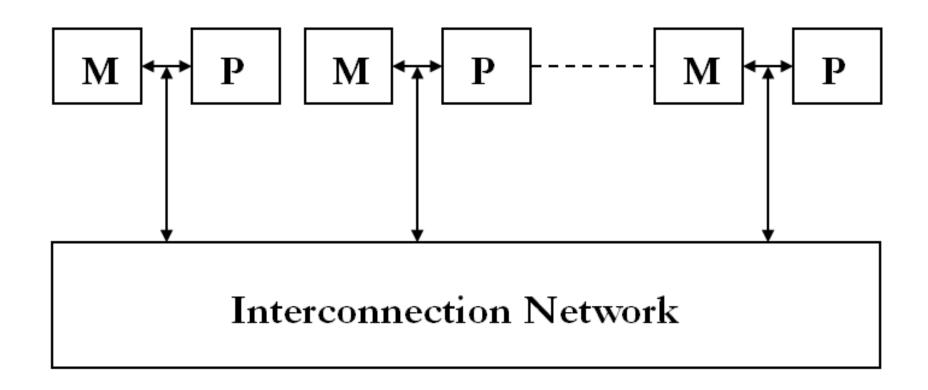

## **Uniform Memory Access (UMA)**

## Non-Uniform Memory Access (NUMA) with Local and Global Memories

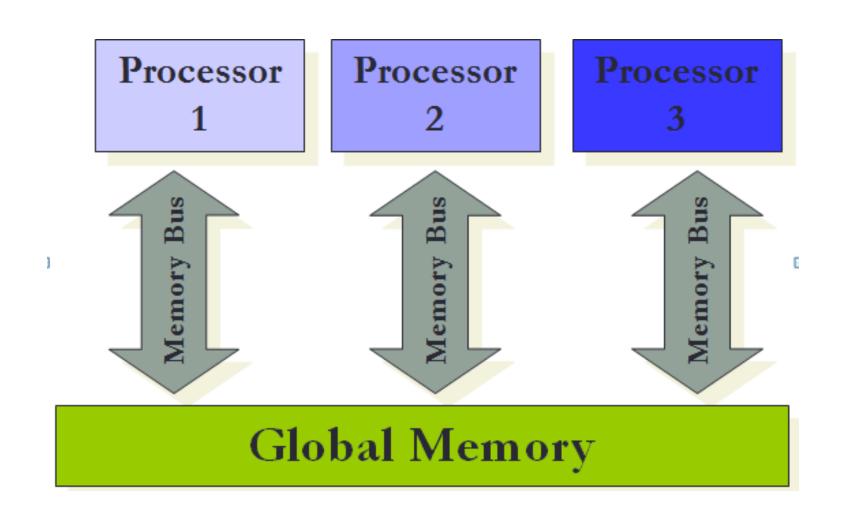

# Non-Uniform Memory Access (NUMA) with Local Memory only

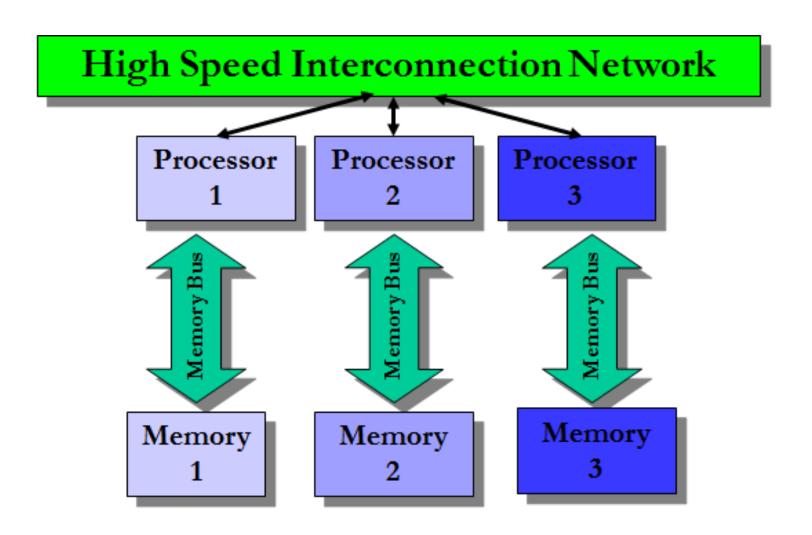

## Shared-Address-Space versus Shared Memory

- We refer to 'shared address space' as a programming abstraction and to 'shared memory' as a physical machine attribute.
  - Shared Memory memory is physically shared among various processors (Each processor has equal access to any memory segment) ... UMA?
  - Distributed Memory different segments of memory are physically associated with different processing elements ... NUMA?
- Both models can provide a logical view of shared address space platform.

## **Shared Memory Architecture**

## **Distributed Memory Architecture**

## **Message-Passing Platforms**

- These platforms comprise of a set of processors and their own (exclusive) memory.
- Instances of such a view come naturally from clustered workstations and non-shared-addressspace multicomputers.
- Interactions between processes running on different nodes must be accomplished using messages

## **Message-Passing Platforms**

- The exchange of messages is used to transfer data, work and to synchronize actions among the processes
- These platforms are programmed using (variants of) send and receive primitives.
- Libraries such as MPI and PVM provide such primitives.

#### Message Passing vs Shared Memory

- Message passing requires little hardware support, other than a network.
- Shared memory platforms can easily emulate message passing.
- The reverse is more difficult to do (in an efficient manner).

### Message Passing vs Shared Memory

Aspect	Shared Memory	Message Passing
Communication	Implicit	Explicit
Synchronization	Explicit	Implicit
Hardware Support	Typically Required	Required as number of processors becomes large
Development Effort	Lower	Higher
Communication Granularity	Finer	Coarser
